ABSTRACT OF THE THESIS

The Effect of Sea Surface Temperature on Sea Breeze Dynamics
Along the Coast of New Jersey

By: Louis A. Bowers

Thesis Director:
Prof. Scott M. Glenn

The New Jersey sea breeze phenomenon is an important mesoscale feature during the warmer months of the year that can dramatically impact sensible weather in the coastal region of the state. Inaccurate meteorological forecasts of the sea breeze can have important ramifications for the public, marine, aviation, and public utility sectors in the heavily tourist laden coastal zone. This can lead to significant losses in terms of tourist dollars, as well as a lack of availability of energy during periods of peak demand, leading to brownouts on hot summer afternoons. Additionally, recirculation of air within the sea breeze circulation can lead to increases in pollution and any accidental or intentional release of toxic chemicals in the coastal zone.

The sea breeze is the result of the differential heating rates of the land and sea. The local temperature gradient near the immediate shoreline determines the behavior of the sea breeze; i.e. wind speed, temperature decrease, inland penetration, and sea breeze frontal shape. The behavior of the sea breeze is observed using visible imagery from satellites and radar reflectivity returns from National Weather Service Doppler radar, and the characteristics of the sea breeze can be monitored through the use of surface observations of wind, temperature, and relative humidity. Local variations in ocean
temperature due to coastal upwelling can impact the behavior of the sea breeze by increasing locally the magnitude of the land – sea temperature gradient in the coastal zone.

A mesoscale model was used to simulate two sea breeze case studies utilizing different ocean temperatures to study the sensitivity of sea breeze behavior to coastal upwelling. The results of these case studies convincingly show the effect of coastal upwelling on the sea breeze, and the importance of the inclusion of high-resolution sea surface temperature data in model simulations of the sea breeze phenomenon.
Acknowledgments

I would like to begin by thanking the Office of Naval Research, NOAA’s Cooperative Program for Operational Meteorology, Education and Training (COMET) Program, and the New Jersey Board of Public Utilities, and the Institute of Marine and Coastal Sciences (IMCS) at Rutgers University whose financial support helped to make this thesis possible. I would also like to thank the meteorological staff at the National Weather Service Forecast Office in Mount Holly, NJ, and especially Alan Cope for providing data crucial to this study over the past few years. I would like to thank the staff at the National Center for Atmospheric Research (NCAR) for their assistance compiling and using the WRF model software.

I would like to convey my deepest appreciation and gratitude for the support of my mentors on this project and throughout my undergraduate and graduate career, Dr. Scott Glenn, Dr. Richard Dunk, and James Eberwine. This thesis would not have been possible without their continuing guidance and assistance these past few years.

My sincerest thanks go out to the IMCS Computing Services team of Adam Porter, Charles J. Belmonte, and Robert Sharry for their help in setting up and maintenance of the computer systems critical to run the WRF model.

I would like to thank all of the support and friendship of the members of the Rutgers University Coastal Ocean Observation Lab (RU COOL) and my fellow graduate students.

I would not be here today without the never-ending support and love of my family, who always pushed me to reach for the clouds and beyond.

Finally I would like to thank my wonderful fiancée Suzanne, whose tremendous caring, emotional support, and understanding have allowed me to keep focused and to continue on with this project even during the worst of times.
